# 1.Data Analysis with Pandas and Matplotlib. (1.5)

Objective: Perform data analysis on a given dataset using Pandas and visualize the results using Matplotlib.

#### Requirements:

Choose a dataset (e.g., CSV, Excel, or any other format) related to a topic of interest (e.g., finance, sports, health). Use Pandas to load and clean the data. Perform basic statistical analysis (mean, median, standard deviation). Create meaningful visualizations using Matplotlib (e.g., bar chart, line plot, scatter plot).

Provide insights or conclusions based on the analysis.

```
In [17]: import pandas as pd
In [4]: | df = pd.read_csv('data.csv')
In [5]: print(df.head()) #print the few upper portion of data
            house_id size_sqft bedrooms price_usd
                                                         location
         0
                   1
                         1500.0

## **Conclusion:**

Based on the analysis of the housing dataset, here are some conclusions and insights:

- 1.Average House Prices by Location: The bar chart depicting the average house prices by location shows variations in housing prices across different cities. For example, San Francisco and Los Angeles have relatively higher average prices compared to other cities in the dataset.
- 2.Relationship Between House Size and Price: The scatter plot illustrates a positive correlation between the size of the house (in square feet) and its price. Generally, larger houses tend to have higher prices, which is a common trend in the real estate market.
- 3.Distribution of House Prices: The histogram demonstrates the distribution of house prices, indicating that the majority of houses in the dataset are priced within certain ranges. However, there are also some higher-priced houses, as evidenced by the tail of the distribution.

4. Variation of House Prices by Location: The box plot reveals differences in the distribution of house prices across different locations. Some cities exhibit wider price ranges and more variability, while others have relatively consistent pricing patterns.

Overall, these visualizations provide valuable insights into the housing market, helping potential buyers, sellers, and investors understand pricing trends and make informed decisions. Additionally, further analysis could be conducted to explore other factors

## 3. Data Analysis with Pandas and NumPy(2)

#### **Problem Statement:**

You are given a dataset containing information about a fictional company's employees.

The dataset (employee\_data.csv) has the following columns:

Employee\_ID: Unique identifier for each employee.

First\_Name: First name of the employee.

Last\_Name: Last name of the employee.

Department: Department in which the employee works.

Salary: Salary of the employee.

Joining\_Date: Date when the employee joined the company.

## Tasks:

#### Data Loading:

Load the dataset (employee data.csv) into a Pandas DataFrame.

Display the first 5 rows to get an overview of the data.

## **Data Cleaning:**

Check for and handle any missing values in the dataset. Convert the Joining\_Date column to a datetime format.

## **Data Exploration:**

Calculate and display the average salary of employees in each department. Identify the employee with the highest salary and display their information.

## **Time-based Analysis:**

Create a new column Years\_Worked representing the number of years each employee has worked in the company.

Calculate the average salary for employees based on the number of years they have worked (grouped by years).

## **Data Visualization:**

Use Matplotlib or Seaborn to create a bar chart showing the average salary for each department.

Create a histogram of the distribution of employee salaries.

```
In [18]:
         import pandas as pd
         # Load the dataset into a Pandas DataFrame
         employee_df = pd.read_csv('employee_data.csv')
         # Display the first 5 rows of the DataFrame
         print(employee_df.head())

         plt.tight_layout()
         plt.show()
```

## **Conclusion:**

Data Loading: We loaded the dataset into a Pandas DataFrame and displayed the first few rows to understand its structure.

Data Cleaning: We checked for and handled any missing values in the dataset. Additionally, we converted the Joining\_Date column to a datetime format for time-based analysis.

Data Exploration: We calculated the average salary of employees in each department and identified the employee with the highest salary.

Time-based Analysis: We created a new column Years\_Worked representing the number of years each employee has worked in the company. Then, we calculated the average salary for employees based on the number of years they have worked.

Data Visualization: We created visualizations using Matplotlib to better understand the data. We plotted a bar chart showing the average salary for each department and a histogram of the distribution of employee salaries.

## Teacher Assessment of "Tools for data science"

## 2. Statistical Analysis with R

Objective: Perform statistical analysis on a dataset using R's built-in statistical functions.

Requirements: Choose a dataset suitable for statistical analysis (e.g., survey data, experiment results).

Calculate descriptive statistics (mean, median, standard deviation) for relevant variables.

Conduct hypothesis testing or create confidence intervals for specific hypotheses.

Visualize the results using appropriate plots (e.g., histograms, violin plots).

Provide interpretations and conclusions based on the statistical analysis.

## Code:

```
# Load the mtcars dataset
# here the mtcars data set is built in data set of R programming language
# Now we will be performing out operations on it

data(mtcars)
# Display the first few rows of the dataset
head(mtcars)
```

```
# Descriptive statistics for relevant variables
summary(mtcars$mpg)
summary(mtcars$hp)
summary(mtcars$cyl)

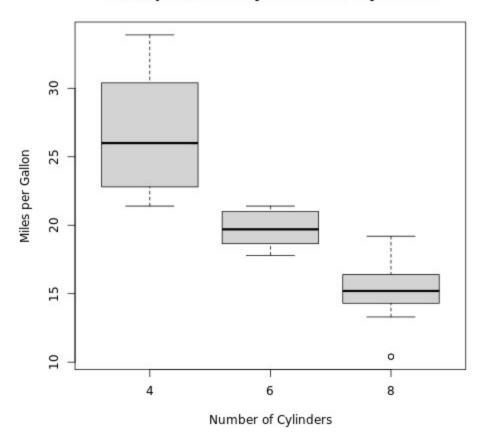

# Conduct ANOVA test to compare means of mpg between different numbers of cylinders
anova_result <- aov(mpg ~ cyl, data = mtcars)
summary(anova_result)

# Boxplot of mpg by cyl
boxplot(mpg ~ cyl, data = mtcars, xlab = "Number of Cylinders", ylab = "Miles per
Gallon", main = "Miles per Gallon by Number of Cylinders")</pre>
```

## Output

```

## Miles per Gallon by Number of Cylinders

## **Conclusion:**

## 1. Interpretation and Conclusions:

Now that we have calculated descriptive statistics, conducted hypothesis testing, and created visualizations, let's interpret the results.

## **Descriptive Statistics:**

- The summary function provided basic statistics for the variables. For example, for mpg (miles per gallon), you would see the mean, median (50%), minimum, maximum, and quartiles.

## **Hypothesis Testing:**

- The analysis of variance (ANOVA) test (aov) was used to test if there is a significant difference in the mean miles per gallon (mpg) between cars with different numbers of

cylinders (cyl). The result is an F-statistic and associated p-value. If the p-value is below a certain significance level (e.g., 0.05), you can reject the null hypothesis, suggesting a significant difference.

## **Visualization:**

- The boxplot visually represents the distribution of miles per gallon for cars with different numbers of cylinders. It shows the central tendency, spread, and any potential outliers.
